- Example

This example demonstrates the usage of std::packaged_task in multithreaded programs.

WE'LL COVER THE FOLLOWING

Example

```
// packagedTask.cpp

#include <utility>
#include <future>
#include <iostream>
#include <thread>
#include <deque>

class SumUp{
  public:
    int operator()(int beg, int end){
      long long int sum{0};
      for (int i = beg; i < end; ++i ) sum += i;
      return sum;
    }
};

int main(){

  std::cout << std::endl;

  SumUp sumUp1;
  SumUp sumUp2;
  SumUp sumUp3;
  SumUp sumUp4;

  // wrap the tasks
  std::packaged_task<int(int, int)> sumTask1(sumUp1);
  std::packaged_task<int(int, int)> sumTask2(sumUp2);
  std::packaged_task<int(int, int)> sumTask3(sumUp3);
  std::packaged_task<int(int, int)> sumTask4(sumUp4);

  // create the futures
  std::future<int> sumResult1 = sumTask1.get_future();
  //std::future<int> sumResult2 = sumTask2.get_future();
```

```
  auto sumResult2 = sumTask2.get_future();
  std::future<int> sumResult3 = sumTask3.get_future();
  //std::future<int> sumResult4 = sumTask4.get_future();
  auto sumResult4 = sumTask4.get_future();

  // push the tasks on the container
  std::deque<std::packaged_task<int(int,int)>> allTasks;
  allTasks.push_back(std::move(sumTask1));
  allTasks.push_back(std::move(sumTask2));
  allTasks.push_back(std::move(sumTask3));
  allTasks.push_back(std::move(sumTask4));

  int begin{1};
  int increment{2500};
  int end = begin + increment;

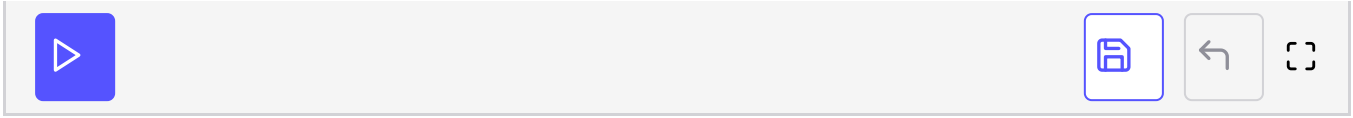
  // execute each task in a separate thread
  while (not allTasks.empty()){
    std::packaged_task<int(int, int)> myTask = std::move(allTasks.front());
    allTasks.pop_front();
    std::thread sumThread(std::move(myTask), begin, end);
    begin = end;
    end += increment;
    sumThread.detach();
  }

  // get the results
  auto sum = sumResult1.get() + sumResult2.get() +
             sumResult3.get() + sumResult4.get();

  std::cout << "sum of 0 .. 10000 = " << sum << std::endl;

  std::cout << std::endl;

}
```



Explanation

The purpose of the program is to calculate the sum of all numbers from 0 to 10000 with the help of four `std::packaged_task`, each running in a separate thread. The associated futures are used to sum up the final result. Of course, you can also use the Gaußschen Summenformel.

I. **Wrap the tasks**: We pack the work packages in `std::packaged_task` (lines 28 - 31) objects. Work packages are instances of the class `SumUp` (lines 9 - 16). The work is done in the call operator (lines 11 - 15) which sums up all numbers from `beg` to `end - 1` and returns the sum as a result. `std::packaged_task` (lines 28 - 31) can handle the callables that need two `int`s and return an `int`: `int(int, int)`.

II. **Create the futures**: We must create `future` objects with the help of `std::packaged_task` objects (lines 34 to 39). The `packaged_task` is the promise in the communication channel. The type of the `future` is defined explicitly: `std::future<int> sumResult1= sumTask1.get_future()`. The compiler can complete the task for us: `auto sumResult1= sumTask1.get_future()`.

III. **Perform the calculations**: Now the calculation occurs. The `packaged_task` are moved onto the `std::deque` (lines 43 - 46). In the while loop, each `packaged_task` (lines 54 - 59) is executed. To complete the task, we move the head of the `std::deque` in a `std::packaged_task` (line 54). We then move the `packaged_task` in a new thread (line 56) and let it run in the background (line 59). We used the move semantic in lines 54 and 56 since `std::packaged_task` objects are not copyable. This restriction holds for all promises, futures, and threads. There is one exception to this rule: ***std:.shared_future***.

IV. **Pick up the results**: In the final step, we ask all futures for their value and sum them up (line 63-64).

Test your knowledge on this topic with an exercise in the next lesson.
