

# Challenge 1: Calculating Perimeter of a Rectangle

In this lesson, you will solve a challenge to test your understanding of classes.

## WE'LL COVER THE FOLLOWING ^

- Problem Statement
  - Input
  - Output
  - Sample Input
  - Sample Input
- Coding Exercise
  - Solution Review

## Problem Statement #

Write a *class* having **two** `float` type variables for `length` and `height`, a **default constructor** and **one member** function called `perimeter` which will *return* the **perimeter** of the **rectangle**.

## Input #

Length and width of the rectangle

## Output #

Perimeter of rectangle

## Sample Input #

```
length = 2, height = 10
```

## Sample Input #

Finding the perimeter of rectangle

## Coding Exercise #

This problem is designed for your practice so try to solve it on your own first. If you get stuck, you can always refer to the solution provided in the solution section.

**Good Luck!**

 Exercise

 Solution

```
// Define Rectangle class here
// Add public data members and member function

float calculate(float length, float height) {

    // Make rectangle object and set length and height here

    float answer;

    // Store rectangle perimeter in answer
    return answer;
}
```

## Solution Review #

- Firstly, a class `Rectangle` is made with the data members `length` and `height`

- A Constructor initializes the data members to zero.
  - The function `perimeter` calculates the perimeter from data members
  - Inside the `main` function, an object `obj` of class Rectangle is made
  - After assigning the relevant values to data members, the `perimeter` function is called which returns the perimeter of a rectangle
- 

In the next challenge, we'll solve another problem of calculating the total marks of the student.
