

# Declaring Non-Type Template Parameters With auto

This lesson teaches you how C++ 17 uses auto for deducing non-type template parameters.

This is another part of the strategy to use `auto` everywhere. With `C++11` and `C++14` you can use it to deduce variables or even return types automatically, plus there are also generic lambdas. Now you can also use it for deducing non-type template parameters. For example:

```
template <auto value> void f() { }  
...  
f<10>(); // deduces int
```

This is useful, as you don't have to have a separate parameter for the type of non-type parameter. *Like in C++11/14:*

```
template <typename Type, Type value> constexpr Type TConstant = value;  
...  
constexpr auto const MySuperConst = TConstant<int, 100>;
```

*With C++17 it's a bit simpler:*

```
template <auto value> constexpr auto TConstant = value;  
...  
constexpr auto const MySuperConst = TConstant<100>;
```

No need to write `Type` explicitly.

As one of the advanced uses a lot of papers, and articles point to an example of heterogeneous compile time list:

```
template <auto ... vs> struct HeterogenousValueList {};  
...  
using MyList = HeterogenousValueList<'a', 100, 'b'>;
```

*Before C++17 it was not possible to declare such list directly, some wrapper*

class would have had to be provided first.

**Extra Info:** The change was proposed in: [P0127R2](#). In [P0127R1](#), you can find some more examples and reasoning

---

The next lesson will conclude this section with the description of some other modifications in C++ 17.
