

Static Versus Dynamic Polymorphism

Let's dive deep into polymorphism in this lesson.

WE'LL COVER THE FOLLOWING ^

- Polymorphism

Polymorphism

Polymorphism means that an object can have different behaviors.

- **Dynamic Polymorphism**

- Polymorphism happens at runtime.
- A key feature of object-orientation.
- Based on interfaces and virtual methods.
- Needs one indirection such as a reference or a pointer in C++.

- **Static Polymorphism**

- Polymorphism happens at compile-time.
- Is not bound to interfaces or derivation hierarchies => [Duck Typing](#)
- No indirection such as pointers or references required.
- Static polymorphism is typically faster than dynamic polymorphism.

In the next lesson, we'll discuss a couple of examples of polymorphism.
