- Solutions

Let's look at the solutions of the exercises from the last lesson.

Solution of problem statement 1

```
// templateCRTPRelational.cpp

#include <iostream>
#include <string>
#include <utility>

template<class Derived>
class Relational{};

// Relational Operators

template <class Derived>
bool operator > (Relational<Derived> const& op1, Relational<Derived> const & op2){
    Derived const& d1 = static_cast<Derived const&>(op1);
    Derived const& d2 = static_cast<Derived const&>(op2);
    return d2 < d1:</pre>
```

```
recuiii uz \ uij
template <class Derived>
bool operator == (Relational<Derived> const& op1, Relational<Derived> const & op2){
    Derived const& d1 = static_cast<Derived const&>(op1);
    Derived const& d2 = static_cast<Derived const&>(op2);
    return !(d1 < d2) && !(d2 < d1);
}
template <class Derived>
bool operator != (Relational<Derived> const& op1, Relational<Derived> const & op2){
    Derived const& d1 = static_cast<Derived const&>(op1);
    Derived const& d2 = static_cast<Derived const&>(op2);
    return (d1 < d2) || (d2 < d1);
template <class Derived>
bool operator <= (Relational<Derived> const& op1, Relational<Derived> const & op2){
    Derived const& d1 = static_cast<Derived const&>(op1);
    Derived const& d2 = static_cast<Derived const&>(op2);
    return (d1 < d2) || (d1 == d2);
template <class Derived>
bool operator >= (Relational<Derived> const& op1, Relational<Derived> const & op2){
    Derived const& d1 = static_cast<Derived const&>(op1);
    Derived const& d2 = static_cast<Derived const&>(op2);
    return (d1 > d2) \mid \mid (d1 == d2);
}
// Apple
class Apple: public Relational<Apple>{
public:
    explicit Apple(int s): size{s}{};
    friend bool operator < (Apple const& a1, Apple const& a2){</pre>
        return a1.size < a2.size;</pre>
private:
    int size;
};
// Man
class Man: public Relational<Man>{
public:
    explicit Man(const std::string& n): name{n}{}
    friend bool operator < (Man const& m1, Man const& m2){</pre>
        return m1.name < m2.name;</pre>
private:
    std::string name;
};
// class Person
class Person: public Relational<Person>{
public:
    Person(std::string fst, std::string sec): first(fst), last(sec){}
    friend bool operator < (Person const& p1, Person const& p2){</pre>
        return std::make_pair(p1.first, p2.last) < std::make_pair(p2.first, p2.last);</pre>
private:
```

```
std::string first;
    std::string last;
};
int main(){
  std::cout << std::boolalpha << std::endl;</pre>
  Apple apple1{5};
  Apple apple2{10};
  std::cout << "apple1 < apple2: " << (apple1 < apple2) << std::endl;</pre>
  std::cout << "apple1 > apple2: " << (apple1 > apple2) << std::endl;</pre>
  std::cout << "apple1 == apple2: " << (apple1 == apple2) << std::endl;</pre>
  std::cout << "apple1 != apple2: " << (apple1 != apple2) << std::endl;</pre>
  std::cout << "apple1 <= apple2: " << (apple1 <= apple2) << std::endl;</pre>
  std::cout << "apple1 >= apple2: " << (apple1 >= apple2) << std::endl;</pre>
  std::cout << std::endl;</pre>
 Man man1{"grimm"};
 Man man2{"jaud"};
  std::cout << "man1 < man2: " << (man1 < man2) << std::endl;</pre>
  std::cout << "man1 > man2: " << (man1 > man2) << std::endl;</pre>
  std::cout << "man1 == man2: " << (man1 == man2) << std::endl;</pre>
  std::cout << "man1 != man2: " << (man1 != man2) << std::endl;</pre>
  std::cout << "man1 <= man2: " << (man1 <= man2) << std::endl;</pre>
  std::cout << "man1 >= man2: " << (man1 >= man2) << std::endl;</pre>
  std::cout << std::endl;</pre>
  Person rainer{"Rainer", "Grimm"};
  Person marius{"Marius", "Grimm"};
  std::cout << "rainer < marius: " << (rainer < marius) << std::endl;</pre>
  std::cout << "rainer > marius: " << (rainer > marius) << std::endl;</pre>
  std::cout << "rainer == marius: " << (rainer == marius) << std::endl;</pre>
  std::cout << "rainer != marius: " << (rainer != marius) << std::endl;</pre>
  std::cout << "rainer <= marius: " << (rainer <= marius) << std::endl;</pre>
  std::cout << "rainer >= marius: " << (rainer >= marius) << std::endl;
  std::cout << std::endl;</pre>
}
```

In the code above, we have defined the Person class which contains the string variables, first and last and a < operator to compare two people's lengths in lines 75 – 77. The class Person is publicly derived (line 72) from the class Relational < Person >. We have implemented (for classes of the kind Relational) the greater than operator > (lines 12 - 17), the equality operator == (lines 19 - 24), the not equal operator != (lines 26 - 31), the less than or equal operator <= (line 33 - 38) and the greater than or equal operator >=

(lines 40 - 45). The less than or equal and greater than or equal operators use the equality operator (line 37 and 44). All these operators convert their operands to Derived const&: Derived const& d1 = static_cast<Derived const&> (op1).

In the main program, we have compared the Apple, Man, and Person classes for all the operators mentioned above.

Solution of problem statement 2

```
// templateCRTPCheck.cpp
                                                                                             G
#include <iostream>
template <typename Derived>
struct Base{
  void interface(){
    static_cast<Derived*>(this)->implementation();
  void implementation(){
    std::cout << "Implementation Base" << std::endl;</pre>
private:
    Base(){};
    friend Derived;
};
struct Derived1: Base<Derived1>{
  void implementation(){
    std::cout << "Implementation Derived1" << std::endl;</pre>
};
struct Derived2: Base<Derived2>{
  void implementation(){
    std::cout << "Implementation Derived2" << std::endl;</pre>
  }
};
struct Derived3: Base<Derived3>{};
// struct Derived4: Base<Derived3>{};
template <typename T>
void execute(T& base){
    base.interface();
}
int main(){
  std::cout << std::endl;</pre>
  Derived1 d1;
  execute(d1);
  Donivoda da.
```

```
perived2 d2;
execute(d2);

Derived3 d3;
execute(d3);

// Derived4 d4;

std::cout << std::end1;
}</pre>
```

We have used static polymorphism in the function template execute (lines 34 – 37). We invoked the method base.interface on each base argument. The method Base::interface, in lines (7 – 9), is the key point of the CRTP idiom. It dispatches to the implementation of the derived class: static_cast<Derived*> (this)->implementation(), which is possible because the method will be instantiated when called. At this point in time, the derived classes Derived1, Derived2, and Derived3 are fully defined. Therefore, the method Base::interface can use the details of its derived classes. The method Works as the default implementation of the static polymorphism for the class Derived3 (line 30).

The constructor of the derived class has to call the constructor of the base class. The constructor in the base class is private. Only type T can invoke the constructor of the base class. So, if the derived class is different from the class T, the code doesn't compile.

Solution to problem statement 3 (case 1)

```
// dispatchPolymorphism.cpp

#include <iostream>

struct Base{
    virtual void interface(){
        std::cout << "Implementation Base" << std::endl;
    }
};

struct Derived1: Base{
    virtual void interface(){</pre>
```

```
std::cout << "Implementation Derived1" << std::endl;</pre>
};
struct Derived2: Base{
    virtual void interface(){
        std::cout << "Implementation Derived2" << std::endl;</pre>
};
struct Derived3: Base{};
void execute(Base& base){
    base.interface();
}
int main(){
    std::cout << std::endl;</pre>
    Derived1 d1;
    Base b1 = d1;
    execute(b1);
    Derived2 d2;
    Base& b2 = d2;
    execute(b2);
    Derived3 d3;
    Base& b3 = d3;
    execute(b3);
    std::cout << std::endl;</pre>
```

We have used dynamic polymorphism in the function template execute (lines 25 – 27). This function only accepts a reference to the class object passed. Now, we make objects of the derived classes and store references to them (lines 34, 38 and 42). The static type of b1, b2, and b3 in lines 34, 38, 42 is Base and the dynamic type is Derived1, Derived2, or Derived3 respectively.

Solution to problem statement 3 (case 2)

```
virtual void interface(){
        std::cout << "Implementation Base" << std::endl;</pre>
};
struct Derived1: Base{
    virtual void interface(){
        std::cout << "Implementation Derived1" << std::endl;</pre>
};
struct Derived2: Base{
    virtual void interface(){
        std::cout << "Implementation Derived2" << std::endl;</pre>
};
struct Derived3: Base{};
template <typename T>
void execute(T& t){
    t.interface();
int main(){
    std::cout << std::endl;</pre>
    Derived1 d1;
    execute(d1);
    Derived2 d2;
    execute(d2);
    Derived3 d3;
    execute(d3);
    std::cout << std::endl;</pre>
```

We have implemented a template function on lines 25 - 28, which delegates execution to the appropriate <code>interface()</code> function on line 27. <code>Base</code>, <code>Derived1</code>, and <code>Derived2</code> all provide an implementation for the <code>interface()</code> function.

<code>Derived3</code> inherits the implementation from <code>Base</code>.

Solution to problem statement 3 (case 3)

```
#include <iostream>
template <typename T>
concept bool Interface(){
    return requires(T a){
        { a.interface } -> void;
}
struct Base{
    virtual void interface(){
        std::cout << "Implementation Base" << std::endl;</pre>
};
struct Derived1: Base{
    virtual void interface(){
        std::cout << "Implementation Derived1" << std::endl;</pre>
};
struct Derived2: Base{
    virtual void interface(){
        std::cout << "Implementation Derived2" << std::endl;</pre>
};
struct Derived3: Base{};
template <typename Interface>
void execute(Interface& inter){
    inter.interface();
int main(){
    std::cout << std::endl;</pre>
    Derived1 d1;
    execute(d1);
    Derived2 d2;
    execute(d2);
    Derived3 d3;
    execute(d3);
    std::cout << std::endl;</pre>
```

This implementation is based on **concepts** which will be part of C++20. In the

supports a function with the name interface returning void.

Solution to problem statement 4

```
// templatesCRTPShareMe.cpp
                                                                                            G
#include <iostream>
#include <memory>
class ShareMe: public std::enable_shared_from_this<ShareMe>{
public:
 std::shared_ptr<ShareMe> getShared(){
    return shared_from_this();
};
int main(){
  std::cout << std::endl;</pre>
  // share the same ShareMe object
  std::shared_ptr<ShareMe> shareMe(new ShareMe);
  std::shared_ptr<ShareMe> shareMe1= shareMe->getShared();
  // both resources have the same address
  std::cout << "Address of resource of shareMe "<< (void*)shareMe.get() << " " << std::endl;</pre>
  std::cout << "Address of resource of shareMe1 "<< (void*)shareMe1.get() << " " << std::end]</pre>
  // the use_count is 2
  std::cout << "shareMe.use_count(): "<< shareMe.use_count() << std::endl;</pre>
  std::cout << std::endl;</pre>
```

Explanation

With the class std::enable_shared_from_this, we can create objects which return an std::shared_ptr to itself. For that, we have to derive the class public from std::enable_shared_from_this. The smart pointer shareMe (line 18) is copied by shareMe1 (line 19). The call shareMe->getShared() in line 19 creates a new smart pointer. getShared() (line 8) internally uses the function shared_from_this. In lines 22 and 23, shareMe.get() and shareMe1.get() return a pointer to the resource. In line 26, the shareMe.use_count() returns the value of the reference counter.

This concludes our discussion of templates. In the next chapter, we'll study
