Check Permutation

In this lesson, you will learn how to check if a string is a permutation of another string in Python.

WE'LL COVER THE FOLLOWING ^

- Solution 1
 - Implementation
 - Explanation
- Solution 2
 - Implementation
 - Explanation

In this lesson, we will consider how to determine if a given string is a permutation of another string.

Specifically, we want to solve the following problem:

Given two strings, write a function to determine if one is a permutation of the other.

Here is an example of strings that are permutations of each other:

```
is_permutation_1 = "google"
is_permutation_2 = "ooggle"
```

The strings below are not permutations of each other.

```
not_permutation_1 = "not"
not_permutation_2 = "top"
```

We will solve this problem in Python and analyze the time and space complexity of our approach.

Let's hegin!

Solution 1#

Implementation

A permutation of a string will have the same number of each type of character as that string as it is just a rearrangement of the letters.

Let's have a look at the code below where we make use of this property:

```
# Approach 1: Sorting
                                                                                         G
# Time Complexity: O(n log n)
# Space Complexity: 0(1)
def is_perm_1(str_1, str_2):
   str_1 = str_1.lower()
   str_2 = str_2.lower()
   if len(str_1) != len(str_2):
       return False
   str_1 = ''.join(sorted(str_1))
   str_2 = ''.join(sorted(str_2))
   n = len(str_1)
   for i in range(n):
       if str_1[i] != str_2[i]:
            return False
   return True
```

is_perm_1()

Explanation

First of all, both the strings <code>str_1</code> and <code>str_2</code> are normalized on <code>lines 5-6</code> as all the characters are converted to lowercase. On <code>line 8</code>, we check for a basic permutation property, i.e., the two strings that are permutations of each other have to be of the same length. Therefore, <code>False</code> is returned on <code>line 9</code> if the length of <code>str_1</code> does not equal length of <code>str_2</code>.

On **lines 11-12**, both the strings are sorted using the **sorted** function which returns a list. That list is again turned into a string using the **join** function. At this point, **str_1** and **str_2** will be two strings with all the characters sorted in them.

Now if str_1 is a permutation of str_2, all the characters will be the same in the sorted version of both the strings. We'll check this using the for loop on line 16 which runs from i equal 0 to i equal n-1. To traverse the strings,

we make use of n which is set to len(str_1). So, on line 17, we check for the equality of the characters on the same index. If, in any iteration, str_1[i] is not equal to str_2[i], False is returned on line 18. Otherwise, if False is never returned from the function, True is returned on line 19.

As we are using sorting to check for permutations, the time complexity for this solution is O(nlogn) while space complexity is O(1) as there is no extra use of space.

Solution 2

As Solution 1 has O(nlogn) complexity, we need something better. Solution 2 makes use of a hash table to reach a time complexity of O(n).

Implementation

Let's find out how by having a look at the code below:

```
# Approach 2: Hash Table
                                                                                         G
# Time Complexity: O(n)
# Space Complexity: O(n)
def is_perm_2(str_1, str_2):
   str_1 = str_1.lower()
   str_2 = str_2.lower()
    if len(str_1) != len(str_2):
        return False
    d = dict()
    for i in str_1:
        if i in d:
            d[i] += 1
        else:
           d[i] = 1
    for i in str 2:
        if i in d:
            d[i] -= 1
        else:
            d[i] = 1
    return all(value == 0 for value in d.values())
```

is_perm_2()

Explanation

The code from **line 5** to **line 9** is the same as in Solution 1. On **line 11**, d is initialized to a Python dictionary. Using a **for** loop on **line 13** where **i** equals

present in d. If it's present, its value is incremented by 1. After this for loop,

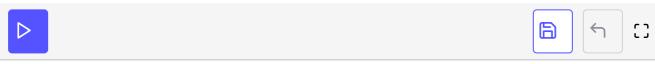

d will have the entire count of all the characters present in str_1. We'll make use of this in the for loop on line 18 where str_2 is traversed. If any character in str_2 is present as a key in d, its value is decremented by 1. If it's not already present in d, it is inserted into d as a key with value equal to 1.

Now, if str_1 and str_1 and str_1 and str_1 and str_1 and str_1 and the values of all the keys in d should be 0. We find this out on line 24 where we evaluate value == 0 for all the keys in d. Using the all function, we combine the evaluation results from all the iterations and return it from the function. The all() function returns True if all items in an iterable are True. Otherwise, it returns False.

In the code widget below, you can execute both the functions on different test cases.

```
# Approach 1: Sorting
# Time Complexity: O(n log n)
# Space Complexity: O(1)
def is_perm_1(str_1, str_2):
   str_1 = str_1.lower()
    str_2 = str_2.lower()
    if len(str_1) != len(str_2):
        return False
    str_1 = ''.join(sorted(str_1))
    str_2 = ''.join(sorted(str_2))
    n = len(str_1)
    for i in range(n):
        if str 1[i] != str 2[i]:
            return False
    return True
# Approach 2: Hash Table
# Time Complexity: O(n)
# Space Complexity: O(n)
def is_perm_2(str_1, str_2):
   str_1 = str_1.lower()
    str_2 = str_2.lower()
    if len(str_1) != len(str_2):
        return False
    d = dict()
```

```
for i in str_1:
        if i in d:
            d[i] += 1
        else:
            d[i] = 1
    for i in str_2:
        if i in d:
            d[i] -= 1
        else:
            d[i] = 1
    return all(value == 0 for value in d.values())
is_permutation_1 = "google"
is_permutation_2 = "ooggle"
not_permutation_1 = "not"
not_permutation_2 = "top"
print(is_perm_1(is_permutation_1, is_permutation_2))
print(is_perm_1(not_permutation_1, not_permutation_2))
print(is_perm_2(is_permutation_1, is_permutation_2))
print(is_perm_2(not_permutation_1, not_permutation_2))
```

Now that you are pretty familiar with the problems regarding string processing, it's test time! Brace yourselves for the upcoming challenge!
