# Firebase Hosting

Let's take a look at how Firebase can host our web application.

We can use Firebase to host our project on top of Google's infrastructure.
Navigate to the **Hosting** option to get started on deployment.

First, we need to install the necessary node packages on the command line.

Then we can login with a Google account, initialize a Firebase application, and finally deploy it.

It's worth mentioning that Firebase Hosting comes with all essential features (e.g. analytics, domain support) that other hosting providers would offer as well.

Now that we know how to setup Firebase, we are ready to create and deploy a React application on the platform.
